## Confidence Intervals

Diana Mindrila, Ph.D.

Phoebe Balentyne, M.Ed.

Based on Chapter 14 of The Basic Practice of Statistics (6 $6^{\text {th }}$ ed.)

## Concepts:

- The Reasoning of Statistical Estimation
- Margin of Error and Confidence Level
- Confidence Intervals for a Population Mean
- How Confidence Intervals Behave

## Objectives:

$>$ Define statistical inference.
$>$ Describe the reasoning of statistical estimation.
$>$ Describe the parts of a confidence interval.
$>$ Interpret a confidence level.
$>$ Construct and interpret a confidence interval for the mean of a Normal population.
> Describe how confidence intervals behave.

## Statistical Inference

* The purpose of collecting data on a sample is not simply to have data on that sample. Researchers take the sample in order to infer from that data some conclusion about the wider population represented by the sample.

Statistical Inference
Statistical inference provides methods for drawing conclusions about a population from sample data.

- These notes will cover how to estimate the mean of a variable for the entire population after computing the mean for a specific sample.
- For example, a researcher is interested in estimating the achievement motivation of first year college students. The researcher must select a random sample of students, administer a motivation scale, and then compute the average score for the entire sample. Based on this average score, he or she can then make an inference about the motivation of the entire population of first year college students.

## Simple Conditions for Inference about a Mean

There are certain requirements that must be met before making inferences about a population mean:

1) The sample must be randomly selected.
2) The variable of interest must have a Normal distribution $N(\mu, \sigma)$ in the population.
3) The population mean $\mu$ is unknown, but the standard deviation $\sigma$ for the variable must be known.

- These conditions are very difficult to meet in a real situation, especially in social science research.
- There are other procedures that need to be followed when these conditions are not met.
- These notes will start by discussing the best-case scenario, when all the conditions are met.

## Statistical Estimation

* Statistics - observed values; computed based on the sample data
* Parameters - estimated values; estimated based on sample statistics

Example:

Motivation Scale:
$\mathrm{N}=400$
Sample Mean $=80$

What is the population mean on this motivation scale?

- In this example, the same mean is 80.
- It is not likely that the population mean would be the same as the sample mean since it is a different set of individuals.
- In order to estimate the population mean, the standard deviation of this variable in the population must be known.

## Estimating the Population Mean

## Confidence Level

The confidence level is the overall capture rate if the method is used many times. The sample mean will vary from sample to sample, but the method estimate $\pm$ margin of error is used to get an interval based on each sample. C\% of these intervals capture the unknown population mean $\mu$. In other words, the actual mean will be located within the interval C\% of the time.

## Confidence interval $=$ sample mean $\pm$ margin of error

- The population mean for a certain variable is estimated by computing a confidence interval for that mean.
- If several random samples were collected, the mean for that variable would be slightly different from one sample to another. Therefore, when researchers estimate population means, instead of providing only one value, they specify a range of values (or an interval) within which this mean is likely to be located.
- To obtain this confidence interval, add and subtract the margin of error from the sample mean. This result is the upper limit and the lower limit of the confidence interval. The confidence interval may be wider or narrower depending on the degree of certainty, or estimation precision, that is required.

## Example:

Sample mean=80
Margin of error=3.92
Confidence level (CI): 95\%
$\mathrm{Cl}(95 \%)=80 \pm 3.92$
Upper limit $=80+3.92=83.92$
$] C I(95 \%)=(76.08 ; 83.92)$
*Researchers can say, with $95 \%$ confidence that the population mean on the motivation scale is between 76.08 and 83.92.

## Margin of Error

- In order to find a confidence interval, the margin of error must be known.
- The margin of error depends on the degree of confidence that is required for the estimation.
- Typically degrees of confidence vary between $90 \%$ and $99.9 \%$, but it is up to the researcher to decide.

## Margin of error $=z^{*} \cdot \frac{\text { population standard deviation }}{\sqrt{n}}$

- The level of confidence is represented by $z^{*}$ (called z star).
- It is also necessary to know the standard deviation of the variable in the population. (Note: the population standard deviation is NOT the same as the sample standard deviation).
- Finally, the size of the sample $n$ will be used to compute the margin of error.

## Example:

## $\mathrm{Cl}_{(95 \%)}: \mathrm{z}^{*}=1.96$ <br> $\left(\mathrm{Cl}_{(98 \%)}: z^{*}=2.326 ; \mathrm{Cl}_{(99 \%)}: \mathrm{z}^{*}=2.576\right)$ <br> (find these values in the last row of Table C) <br> Population standard deviation=40 <br> $\mathrm{N}=400$

$$
M E=z^{*} \cdot \frac{\sigma}{\sqrt{n}}
$$

$$
=1.96 \cdot \frac{40}{\sqrt{400}}
$$

$$
=1.96 \cdot \frac{40}{20}
$$

$$
=1.96 \cdot 2
$$

$$
=3.92
$$

- In the above example, a confidence level of $95 \%$ was selected. The value of $z^{*}$ for a specific confidence level is found using a table in the back of a statistics textbook. The value of $\mathrm{z}^{*}$ for a confidence level of $95 \%$ is 1.96 .
- After putting the value of $\mathrm{z}^{*}$, the population standard deviation, and the sample size into the equation, a margin of error of 3.92 is found.

## Confidence Intervals

- The formulas for the confidence interval and margin of error can be combined into one formula.

## Example:

What is the $90 \%$ confidence interval for the population mean?
Sample mean $=80$
Population standard deviation $=40$
$\mathrm{N}=400$
$z^{*}=$ ? (use table C to find the value of $z^{*}$ at the $90 \%$ confidence level)

## The Reasoning of Statistical Estimation

Where does the formula for computing a confidence interval come from?

- The true value of the population mean is never known - it can only be approximated or estimated.
- The best way to do this is to select a large number of random samples of the same size from the population.
- The mean from each random sample will be slightly different.
- The average of these sample means is the population mean.

## How would the sample mean $\bar{x}$ vary if many SRSs were taken of the same size from the population?

Shape: Since the population is Normal, so is the sampling distribution of $\bar{x}$.
Center: The mean of the sampling distribution of $\bar{x}$ is the same as the mean of the population distribution, $\mu$.

## Distribution of the variable in the population:

- For instance, the mean for the sample in the example was 80, but if another sample was selected the mean might be 78 or 83 .
- If a large number of sample means were represented graphically, they would have a Normal distribution.
- The mean of this distribution is the same as the sample mean, but the standard deviation of this distribution is equal to the standard deviation of the variable in the population divided by the square root of the sample size.
- This is the reason that the standard deviation is divided by the square root of $n$ in the formula, instead of the simple standard deviation, because this formula represents the standard deviation of the distribution of many sample means.
- When working with real data it may not be feasible to select a very large number of random samples, but if researchers were able to do so, the samples would form a Normal distribution.

## The Reasoning of Statistical Estimation

- If many random samples are collected, their means will have a Normal distribution.
- This means that the 68-95-99.7 Rule can be used to estimate the values within which the population mean would fall.
- Since $95 \%$ of values fall within two standard deviations of the mean according to the 68-95-99.7 Rule, simply add and subtract two standard deviations from the mean in order to obtain the 95\% confidence interval.

If researchers estimate that $\mu$ lies somewhere in the interval 76.08 to 83.92 , they would be calculating an interval using a method that captures the true $\mu$ in about $95 \%$ of all possible samples of this size.

- Notice that with higher confidence levels the confidence interval gets large so there is less precision.
- According to the 68-95-99.7 Rule:
$>$ The 68\% confidence interval for this example is between 78 and 82 .
$>$ The 95\% confidence interval for this example is between 76 and 84 .
$>$ The $99.7 \%$ confidence interval for this example is between 74 and 86.
- Therefore, the larger the confidence level, the larger the interval. There is a trade-off between the two.
- If researchers want to be very certain that their interval includes the population mean, they must extend the interval, so there is less precision.
- For intervals that are not specified in the 68-95-99.7 Rule, $\mathrm{z}^{*}$ can be used to obtain the upper bound and the lower bound of the interval.
- It is important to note that $\mathrm{z}^{*}$ provides more precise estimates than the 68-95-99.7 Rule

## How Confidence Intervals Behave

The z confidence interval for the mean of a Normal population illustrates several important properties that are shared by all confidence intervals in common use.
$>$ The user chooses the confidence level and the margin of error follows.
$>$ Researchers would prefer high confidence with a small margin of error.

- High confidence suggests the method almost always gives correct answers.
- A small margin of error suggests the parameter has been pinned down precisely.

How is a small margin of error obtained?
The margin of error for the $z$ confidence interval is:

$$
z * \cdot \frac{\sigma}{\sqrt{n}}
$$

The margin of error gets smaller when:

- $z^{*}$ gets smaller (the same as a lower confidence level C)
- $\sigma$ is smaller. It is easier to pin down $\mu$ when $\sigma$ is smaller.
- $n$ gets larger. Since $n$ is under the square root sign, four times as many observations are needed to cut the margin of error in half.

## Interpreting the Confidence Level

The confidence level is the overall capture rate if the method is used many times. The sample mean will vary from sample to sample, but when the method estimate $\pm$ margin of error is used to get an interval based on each sample, C\% of these intervals capture the unknown population mean $\mu$.

> To say that there is $95 \%$ confidence is shorthand for " $95 \%$ of all possible samples of a given size from this population will result in an interval that captures the unknown parameter."

State: What is the practical question that requires estimating a parameter?
Plan: Identify the parameter, choose a level of confidence, and select the type of confidence interval that fits the situation.

Solve: Carry out the work in two phases:

1. Check the conditions for the interval that has been chosen.
2. Calculate the confidence interval.

Conclude: Return to the practical question to describe the results in this setting.
